# Exploiting Existing Operational Margins by Model-Based Control

## Current control concepts

- Conservative design for worst engine in worst operating condition
- Control schedules not adapted to individual state and actual requirement
- Engine does not operate at its potential optimum

## Approach of model-based control

- Identify the actual state of the engine
- Adapt model to individual engine
- Optimize performance within given limits
- Detect failures and substitute signal

- ➔ *Robust model and control*
- ➔ *Adaptive to individual engine*
- ➔ *Full thermodynamic simulation*
- ➔ *Powerful control hardware*

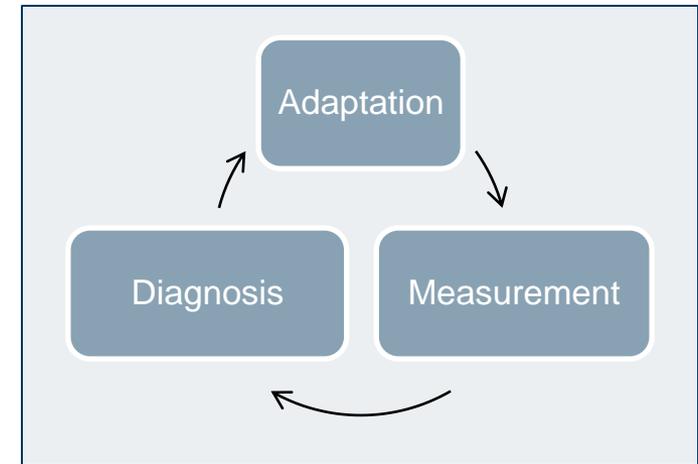

## Improving Component Characteristics by Active Control

### Active control approach

- Identify current condition by sensor or model
  - Modify component behavior by actuators
- ➔ Enhance component characteristic with extended limits
- ➔ Optimized engine cycle design

### Promising technologies include

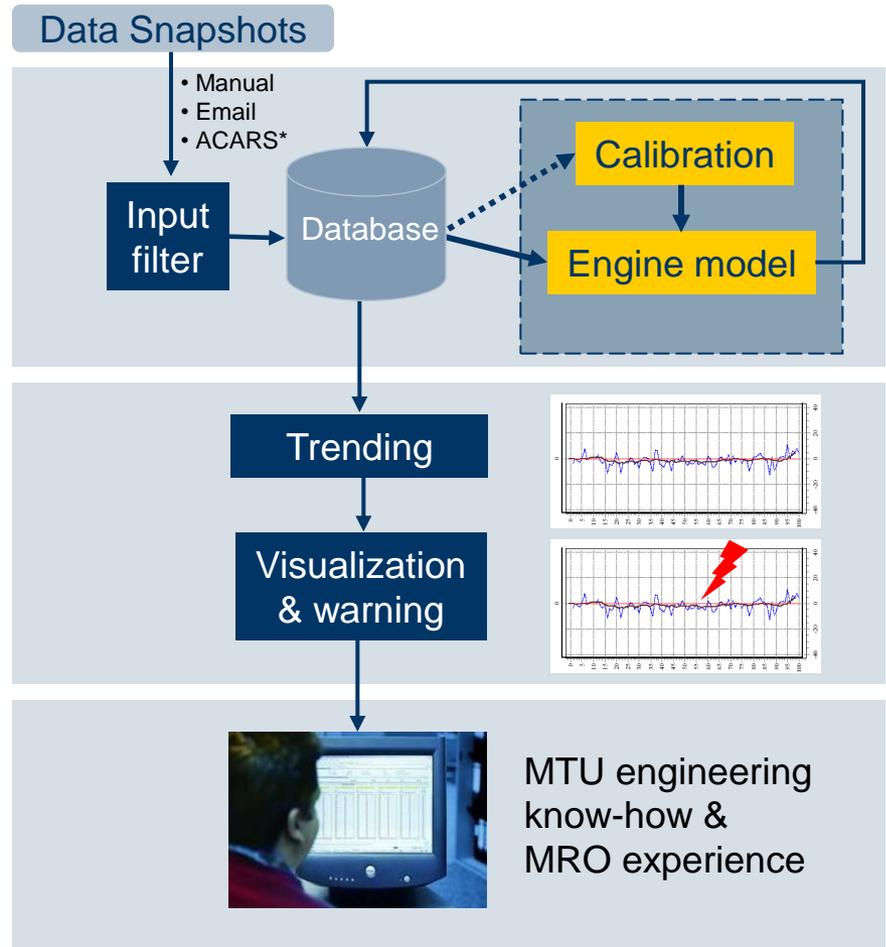

- Active clearance control
- Compressor stability control
- Active flow control
- Turbine cooling air control
- Variable nozzle

# Reducing Operating Cost by Engine Monitoring

- Keeping the engine “in the air” is key interest for operators (traditional) and maintenance providers (Fly-by-Hour)
- Life and fuel savings can be achieved on the basis of diagnostic and prognostic models
- State of the art ECM allows for detection of incipient failures, avoiding secondary damages
- Future trends:
  - ➔ On-line diagnosis on component level
  - ➔ Off-line improved monitoring (EGT margin, fuel burn analysis)

# Integrating Control Components to an Intelligent Engine

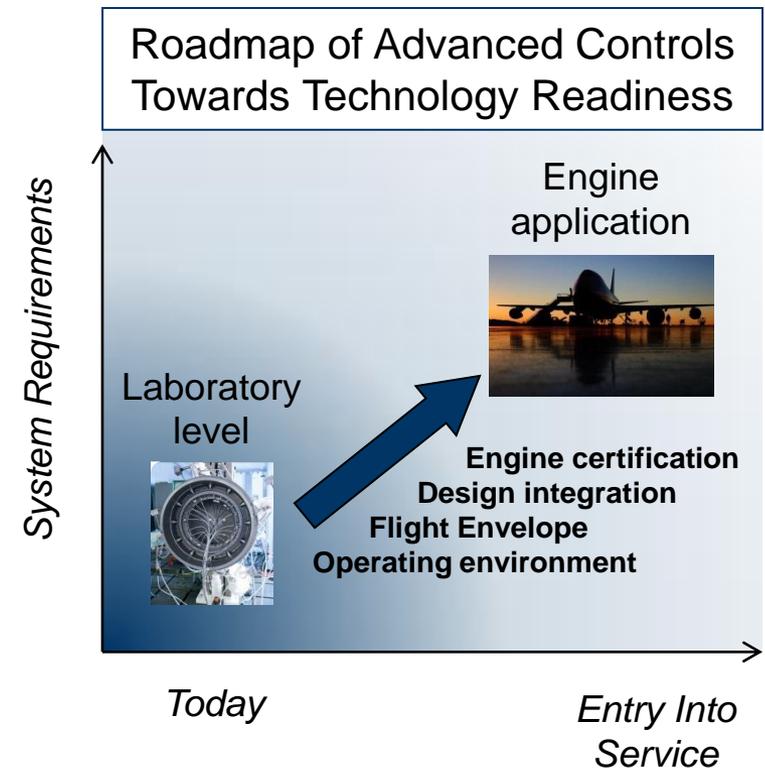

Combining advanced control elements offers large technology potential.

The basis is a robust and individualized diagnostic and prognostic model.

Perspective for intelligent sub-systems and distributed control architecture.

## Challenges on the Way to Technology Readiness

- Meet life and reliability demands
- Reduce in-flight measurement uncertainty
- Reduce weight and size of actuators
- Advanced algorithms for model adaptation
- Increasing complexity of control architecture
- Integration of engine control and aircraft control
- Certification of control system with active and model-based elements

## Conclusion

- Enhanced engine performance controls and diagnostics offer the opportunity to contribute to future air traffic demands.
- The use of models in the control loop is a promising way forward.
- Diagnostic algorithms still have development potential and might become a part of the control system.
- Technologies for active systems have been identified and developed on a laboratory level.
- Technology improvements will be required to reach certification readiness.
